15-112 Fall 2021 Quiz 1b

* Up to 20 minutes. No calculators, no notes, no books, no computers. * Show your work!

* No strings, lists, string or list indexing, loops, or recursion

Code Tracing 1 [20pts]: Indicate what the following code prints. Place your answers (and nothing else) in the box to the right of the code.

```
import math
def ct1(x):
    if (type(x) != int):
        x = 2*x
        return math.ceil(2 * float(str(x)))
    x = abs(x)
    if (x < 0):
        return '0'
    elif (x < 10):
        return x**2
print(ct1(-45))
print(ct1(6))
print(ct1(8.7))
print(ct1('3'))
```

Code Tracing 2 [20pts]: Indicate what the following code prints. Place your answers (and nothing else) in the box to the right of the code.

```
def f(x):
    print(f'f({x})') # Don't miss this line
    return 20+x if (x < 25) else 2*x
def ct2(x):
    if (x % 5 < x % 10):
        x += f(x + f(x))
    return f(x)
print(ct2(15) + ct2(20))
# Hint: this prints 5 lines
```

Free Response 1: isSmallWobble(n) [60 pts]

We will say that a value n is a "wobble" if it is an integer with more odd digits than even digits, but at least one of each. (Ignore leading 0's). A "small wobble" number is a wobble number with exactly 4 digits (thus it must have 1 even and 3 odd digits).

For example, 2133, 1091, and -5792 are small wobble numbers because they have 1 even and 3 odd digits. With this in mind, and without using strings or loops, write the function isSmallWobble(n) that takes a value n, that may or may not be an integer, and returns True if n is a small wobble number, and False otherwise. Do not crash if n is not an integer! **Again, do not use strings or loops here.**

```
def testIsSmallWobble():
    assert(isSmallWobble(1121) == True)
    assert(isSmallWobble(-1091) == True)
    assert(isSmallWobble(1681) == False)
    assert(isSmallWobble(83) == False)
    assert(isSmallWobble('axolotl') == False)
```

Bonus/Optional: Code Tracing [+2.5pts]

Indicate what this prints. Place your answer (and nothing else) in the box.

```
def f(g, h, x): return g(h(x)) + h(g(x))
def g(h): return h**2 + h
def h(g): return g**3 - g + 1
def bonusCt():
    print(f(g,h,1) + f(h,g,2))
bonusCt()
```
